DATA SET DESCRIPTIONS FOR ANALYSES DONE IN THE TEXT
Regression Analysis: A Practical Introduction*, *3rd Edition
Jeremy Arkes

These are in alphabetical order. I do not give the definition for variables with obvious names.

The data sets are available as Stata (.dta) files and comma-delimited (.csv) files.

1. **baseball_payroll_wins**
   This is a cross-sectional data set for the 30 teams in Major League Baseball in the 2013 season. The variables are:
   - **team**
   - **wins** = the number of wins the team had out of the 162 games in the season.
   - **payroll** = the dollar value of all player salaries paid for the season.

2. **dominos**
   This is a notional, 10-observations data set that I created, based on the concept of domino chains. See the text for the errors I created in the chain for some observations, so tipping the first domino, in a few cases, did not lead to the last (5th) domino falling. The variables are:
   - **d1** = whether the first domino fell (or, was tipped)
   - **d3** = whether the 3rd domino fell
   - **d5** = whether the 5th domino fell

3. **gasprices_1994_2003**
   This data set tracks quarterly gas prices over a 10-year period. The variables are:
   - **time** = the time-series-period indicator
   - **price** = U.S. average price of a gallon of gasoline, based on the first Monday of each quarter
   - **year**
   - **qtr** = quarter of the year (1 = winter)
   - **trend** = the same as time, but used as a variable to factor out the trend in prices
   - **yearqtr** = a combination of year-quarter, in the format of 1995Q3

4. **health40_ordered**
   This comes from various rounds of the NLSY starting in 1979. The variables are:
   - **H40** = measure of health for the first observation for the respondent after age 40
   - **educ** = years of schooling completed, as of 2004

- **afqt** = AFQT score
- **male**
- **black**
- **hisp**

5. **health50_females**
   This comes from various rounds of the NLSY starting in 1979, with a sample of just females. The variables are:
   - **H50** = measure of health for the first observation for the respondent after age 50 [ranging from (1 = "poor") to (5 = "excellent")].
   - **H40** = measure of health for the first observation for the respondent after age 40 [same values as for H50].
   - **afqt** = AFQT score
   - **black**

6. **home-prices**
   This cross-sectional dataset has information on homes sold in a California coastal town. Most variables are self-explanatory, but here are key ones:
   - **price** = sale price
   - **sqft** = square feet of house
   - **sqft_lot** = square feet of the property or lot
   - **logprice** = natural logarithm of the price
   - **logsqft** = natural logarithm of the square feet of the house
   - **logsqft_lot** = natural logarithm of the square feet of the lot
   - **bedrooms** = # bedrooms
   - **bathrooms** = # bathrooms
   - **waterfront** = dummy variable for whether the home is on the water
   - **view** = dummy variable for whether the home has a good view
   - **condition** = a rating of 1 (lowest) to 5 (highest) for the condition of the home
   - **cond1**, **cond2**, **cond4**, **cond5** = dummy variables for the condition, with the excluded group being condition=3

7. **income**
   This data set consists of male respondents from the 2004 round of the NLSY starting in 1979. The respondents have positive income and do not have a missing AFQT score—just to be consistent with the data set used in the text. The variables are:
   - **afqt** = Armed Forces Qualification Test score (percentile)
   - **income** = income in 2003 (reported in 2004)
   - **educ** = number of years of schooling completed (e.g., 3 = 3rd grade, 14 = 2 years of college)

- **ageyears** = how old the respondent is (in years) in 2004
- **black** = dummy variable for whether the person is Black
- **hisp** = dummy variable for whether the person is Hispanic
- **coll** = dummy variable for whether the person has a 4-year college degree
- **grad** = dummy variable for whether the person has a graduate degree
- **hs** = dummy variable for whether the person has a high school diploma
- **max_coll** = dummy variable for whether the 4-year college degree is the respondent's highest degree
- **mom_hs** = dummy variable for whether the person's mother has a high school diploma
- **mom_coll** = dummy variable for whether the person's mother has a 4-year college degree
- **dad_hs** = dummy variable for whether the person's mother has a high school diploma
- **dad_coll** = dummy variable for whether the person's mother has a 4-year college degree
- Note that all 4 variables for parents' education are set to zero if the specific parent's education is missing.

8. **instructor_eval_ch4**
   This is notional data I created for the issue of how the class-size affects the evaluations students give instructors. I created data on 100 classes within a university, with 25 classes for each of four professors. I created a certain ranges of class-size and effects of class-size on the average evaluation for each professor (as indicated in Section 4.3). The variables are:
   - **e** = average student evaluation for the course (on a 1-5 scale)
   - **cs** = class size
   - **prof** = identifier for the four professors, A to D
   - **p1-p4** = dummy variables for Professors A to D, respectively.

9. **instructor_eval_ch6**
   This is a separate notional dataset I created for the issue of how the class-size affects the evaluations students give instructors. This dataset is used in Section 6.10. Similar to the one above, I created data on 100 classes within a university, with 25 classes for each of four professors. The effects of class-size on the average evaluation are the same for each professor, but I purposely made different-sized ranges of class-size across the professors (as indicated in Section 6.10). The variables are:
   - **e** = average student evaluation for the course (on a 1-5 scale)
   - **cs** = class size
   - **prof** = identifier for the four professors, A to D

10. insurance-prediction

This notional data set has 10,000 observations. The variables are:

- **y** = whether the person got in an accident
- **accidents10yrs** = number of accidents the person had in the past 10 years
- **colldeg** = whether the person had a college degree
- **age**
- **income**
- **incpct** = percentile of **income.**

11. **japan-n225-ur**

This time-series data set, used throughout Chapter 10, has annual data from Japan. The variables are:

- **year**
- **n225** = annual percentage change in the Nikkei 225 stock-market index
- **ur** = annual Japanese unemployment rate

12. MJ2000

This data comes from the National Longitudinal Survey of Youth, starting in 1997. The sample comes from the 4th round (which occurred in 2000-01), in which the respondents are between 15 and 21 years old. The variables (mostly self-explanatory) are:

- **mj30** = dummy variable for whether the respondent had used marijuana in the past 30 days
- **year** (not used)
- **male**
- racial/ethinic variables (non-Hispanic white is the reference group)
    - **black**
    - **hisp**
    - **other** = dummy variable for a race/ethnicity other race or ethnicity besides Hispanic, non-Hispanic white, and black
- living situation at age 12 (living with both biological parents is the reference group)
    - **one_bio_parent** = lives with just one biological parent
    - **one_bio_other_parent** = lives with one biological parent and another parent
    - **othersit** = has a different situation

13. MJ-UR-new

This data set contains measures of state unemployment rates and marijuana-use rates for 12-17-year-olds at the state level. The state unemployment rates come from the Bureau of Labor Statistics in the U.S. Department of Labor. The marijuana data come from the

National Survey on Drug Use and Health. For this age group, the state use rates are only available as two-year averages. Because of this, I average the state unemployment rate over two-year periods. The two periods are 2006-07 (before the financial crisis) and 2009-10 (which is the heart of the financial crisis). There is one observation per state (plus D.C.), but the measures for the two periods are available. The variables are:

- **statename** = name of state
- **state** = numeric code for state (1-51)
- **ur0607** = average state unemployment rate for 2006-07
- **ur0910** = average state unemployment rate for 2009-10
- **mj0607** = state 30-day-use rate for 12-17-year-olds for 2006-07
- **mj0910** = state 30-day-use rate for 12-17-year-olds for 2009-10
- **urx** = change in the state unemployment rate from 2006-07 to 2009-10
- **mjx** = change in the state 30-day-use rate for 12-17-year-olds from 2006-07 to 2009-10
- **pop2000** = state's 2000 population
- **sqrtpop2000** = square root of state's 2000 population

14. numbirths

This is a sample of females from the 1979 National Longitudinal Survey of Youth. The female must have been aged 16 or 17 in the first round of the survey in 1979, not have had any children yet in that 1979 interview, and answered the question from the 1984 round of the survey on how many children they had. The variables are:

- **numkids84** = number of children they had in the 1984 survey
- **exp_educ** = expected years of schooling they will eventually have
- **age79** = age in the initial 1979 survey
- **afqt** = percentile score on the AFQT
- **black**
- **hisp**

15. sp500

This is a data set with the weekly percent change in the S&P500 Index, as of every Friday from 1/2/2015 to 11/22/2015. The only variables are:

- **date**
- **sp500_pct**

16. sp500_oil_1990_1994 and **sp500_oil_2010_2014**

For two different 5-year periods, these data sets track daily S&P 500 and oil prices. The variables are:

- **period** = time-series indicator of the day number (sequential from 1 to 1266 or 1258
- **sp500** = daily closing price of the S&P 500 index
- **oil** = price of a barrel of oil (based on crude oil, West Texas Intermediate)

17. spurs_win_pct

This data set simply follows the San Antonio Spurs over the history of the franchise while in the NBA (1977-2022). The variables are:

- **year**
- **winpct** = winning percentage for the year
- **lwinpct** = one-year-lagged winning percentage for the year
- **change** = change in winning percentage from the previous year
- **lchange** = one-year-lagged change in winning percentage.

18. study_hours

This is a notional data set that I created. There are just two variables in the original data set:

- **hours** = number of hours studied for an exam
- **score** = score on the exam.

I have one value of *hours* for each number divisible by 0.25 between 0.25 and 18. I make *score* a function of *hours*, with some randomness added in.

19. taxdata

This is annual, time-series data on the United States. There are 28 observations, with data from 1990 to 2017. The variables are:

- **year**
- **taxrate** = maximum marginal income tax rate on individual income in that year
- **urate** = U.S. unemployment rate for the year
- **rgdp** = the growth rate in real Gross Domestic Product

20. tv-bmi-Fig5.1-top/middle/bottom

These 3 data sets contain made-up data. The two variables are:

- **tv** = average number of daily hours of TV (set to represent evenly-spread out values in a given range)
- **bmi** = Body-Mass Index, calculated as follows:
  - 20 + 1.0 × (**tv**) + 12×[a random number between 0 and 1]

21. tv-bmi-med-factor

This is a notional data set of 1000 observations used in Table 6.8. The variables are the following:

- **tv** = average number of daily hours of TV (randomized between 0 and 8)
- **junkfood** = amount of junkfood, calculated as:
  - [a randomized standard normal value] + 0.8×(**tv**)
- **bmi** = Body-Mass Index, calculated as follows:
  - 15 + [a random number between 0 and 5] + 1.0×(**junkfood**) + 0.4×(**tv**)

22. tv-bmi-med-factor (to re-randomize) – available in CSV only

This is the same as the one above, but you can just type a character or number in any cell and it re-randomizes the set on the left so that you can get new numbers to use.

23. tv-bmi-v3

This is a data set of children from the Early Childhood Longitudinal Survey (ECLS), who were kindergartners in 2010-11. This data set was created by the National Center for Education Statistics in the U.S. Department of Education. The ECLS was used in Peck et al. (2015) to examine how TV watching affects children's BMI. (I created the data set from the original data, as the authors' data was not available.) Each observation represents one child, with outcomes over several years. The children are tracked from kindergarten through the 4th grade at the time I use them. The variables that are measured in each wave of the survey have a 2, 4, or 6 at the end of the variable name, corresponding to the Spring semester of, respectively, kindergarten, 1st grade, and 2nd grade. These are for the 2nd, 4th, and 6th waves of the survey. I focus here on the 4th wave. The variables used are:

- **zbmi4** = the standardized body-mass index for the child, condition on his/her gender and age in months
- **tv4** = average hours of TV watching per day, reported by a parent
- **age4** = age in months
- **race4** = racial/ethnic indicator:
- **female**
- **wt4** = sample weight
- Family-income groups (less than $30K to $70K is reference group):
  - **inc4_lt30** = family income is less than $30K
  - **inc4_gt70** = family income is more than $70K

24. us-overdose-deaths

The data on drug overdose deaths come from the Center for Disease Control (https://www.cdc.gov/nchs/pressroom/sosmap/drug_poisoning_mortality/drug_poisoning.htm). I merged in population data and employment statistics. Each observation represents a state for a given year, for 2014-2022. The key variables are:

- **year** and **state**

- **y15-y22** = dummy variables for years 2015 to 2022 (2014 excluded)
- **deaths** = the number of overdose deaths
- **rate** = the number of overdose deaths per 100,000 population
- **ur** = annual state unemployment rate (from the Bureau of Labor Statistics)
- **emppop** = annual state employment-population ratio (from the Bureau of Labor Statistics).
